How much sun is enough?

The sun’s ultraviolet (UV) radiation is both the major cause of skin cancer and the best natural source of vitamin D.

In Australia we need to balance the risk of skin cancer from too much sun exposure with maintaining vitamin D levels.

What is vitamin D and why is it important?

Vitamin D forms in the skin when it is exposed to UVB radiation from sunlight. Some foods, such as oily fish and eggs also contain small amounts of vitamin D, while margarine and some types of milk have added vitamin D. However, food only makes a small contribution to the body’s overall vitamin D levels and it is difficult to get enough from diet alone.

We need vitamin D to maintain good health, in particular to keep bones and muscles strong and healthy.

How much sun do we need for vitamin D?

When the skin is exposed to UV radiation from the sun, vitamin D is formed through a series of processes that start in the skin.

The amount of sunlight you need to make vitamin D depends on a range of factors such as the UV level, your skin type, and your lifestyle. UV levels vary across Australia and throughout the year. Therefore, the amount of time you need to be in the sun to make vitamin D will vary according to your location, the season and the time of day.

Prolonged sun exposure does not cause your vitamin D levels to increase further, but does increase your risk of skin cancer. Short incidental exposure to the sun, such as walking from the office to get lunch, is the best way to produce vitamin D. The amount of vitamin D you make is also related to the amount of skin exposed to the sun – if you expose more of your skin, in most cases you’ll make more vitamin D.

For most people, adequate vitamin D levels are reached through regular incidental exposure to the sun.

When the UV Index is 3 or above (August - May in South Australia), the majority of people maintain adequate vitamin D levels just by spending a few minutes outdoors on most days of the week.

Sensible sun protection does not put people at risk of vitamin D deficiency.

In June and July, when the UV Index typically falls below 3 in southern states, we recommend spending time outdoors in the middle of the day with skin uncovered to support vitamin D production. Being physically active e.g. gardening or going for a brisk walk, also helps boost vitamin D levels.

Daily exercise will also assist your body with the production of vitamin D.
If I protect myself from the sun, will I still get enough vitamin D?

Sensible sun protection does not put people at risk of vitamin D deficiency. When sunscreen is tested in lab conditions it is shown to block vitamin D production, however regular use in real life has been shown to have little effect on vitamin D levels. This is probably because sunscreen doesn’t block 100% of UV radiation so your skin is still exposed to small amounts of UV, even when sunscreen is applied liberally. People who use more sunscreen also spend more time in the sun, so naturally they will have higher vitamin D levels.

When do I need sun protection?

Most Australians need sun protection when the UV Index is 3 or above. The UV Index is an international standard measurement of the strength of UV radiation from the sun at a particular place on a particular day. UV levels are low in the early morning as the sun comes up, gradually increasing to a peak around the middle of the day when the sun is at its highest, and then decreasing slowly as the sun gets lower in the sky.

In the northern parts of Australia (for example Brisbane and Darwin), UV levels are above 3 all year round and reach extreme levels of 14+ in summer, so sun protection is needed daily.

In the southern parts of the country, there are times of the year when sun protection is not necessary. For example, in Adelaide, the average daily UV levels remain below 3 in June and July, so sun protection is not required unless you are outside for extended periods or near highly reflective surfaces like water.

You can refer to the SunSmart UV Alert to find out the sun protection times for your location.

Who is at risk of vitamin D deficiency?

There are groups within the population that are at higher risk of vitamin D deficiency including:

- People with naturally very dark skin. The melanin in dark skin affects UV penetration so you need more UV exposure to make vitamin D.
- People with little or no sun exposure including older adults, especially those who are in residential care or housebound; people who wear concealing clothing for religious or cultural purposes; people who deliberately avoid sun exposure for cosmetic or health reasons; people hospitalised for a long time; people with a disability or chronic disease; night-shift and indoor workers, such as factory workers who have limited incidental UV exposure throughout the day.
- Breast fed babies who fall into the risk categories above or have mothers with low vitamin D. Breast milk contains little vitamin D and infants depend on maternal stores initially. (Formula milk is fortified with vitamin D.)
- People with conditions (obesity, end stage liver disease, renal disease and fat malabsorption syndromes such as cystic fibrosis, coeliac disease, inflammatory bowel disease) or medications affecting vitamin D metabolism.

If you’re at risk of vitamin D deficiency, consult your GP. Vitamin D levels can be checked with a blood test, and your GP can advise on options, such as supplementation, depending on your individual circumstances.

Solariums should never be used to boost vitamin D as they emit dangerous levels of UV that increase your risk of skin cancer.
